Printing with Polymaker™ PC-ABS

Polymaker™ PC-ABS

Polymaker™ PC-ABS is a PC/ABS polymer blend which offers excellent toughness and heat resistance while displaying good surface finish and good compatibility with metal plating.

**Printing settings**

- Nozzle Temperature: 250-270 °C
- Bed Temperature: 90-105 °C
- Chamber Temperature: 90-100 °C
- Printing Speed: 30-50 mm/s
- Cooling Fan: OFF

**Note:** Settings are based on 0.4 mm nozzle, and may vary with different printers and nozzle diameters.

**Bed surface**

Polymaker™ PC-ABS can be printed on almost any surface with a thin coat of Magigoo PC. We recommend a flex plate to facilitate the removal of the model from the plate.
High temperature conditions

We recommend a full metal hot end that can maintain a stable temperature of at least 260°C. We also recommend to use a heated chamber capable of reaching at least 80°C.

Annealing Polymaker™ PC-ABS parts

We recommend annealing all models printed in Polymaker™ PC-ABS. This allows users to take full advantage of the mechanical and thermal properties.

The annealing process consists of putting the model in an oven at 100 °C for 2 hours.

Support material

PolyDissolve™ S2 is the recommended support material for Polymaker™ PC-ABS.

For more information, please visit www.polymaker.com
The profile creation process (PCP) allows users to rapidly develop a printing profile for a given material/printer. It is important to consider all of these factors to build a profile.

Polymaker came up with a process which allows you to build your own profile considering the material, printer and environment. This base profile will then be used to create the custom profile taken in account the model geometry and purpose. Indeed the process is also designed to let you learn more about the 3D printing process and therefore give you the skills and knowledge to troubleshoot your prints.

The PCP is available on www.polymaker.com

The PCP is divided in 5 steps:

- Step 1: Extrusion Flow
- Step 2: Flow Management
- Step 3: Cooling Fan
- Step 4: Warpage
- Step 5: Fine Details

It uses less than 300g of materials and less than 7h of working time.

Each of these steps has a specific objective and introduce an important concept about the FFF 3D printing process. Each step will also give you the possibility to push your test further for more accurate results.

*The flame retardant will significantly reduce the toughness of the raw PC material. Polymaker found the right balance between the mechanical properties and the flame retardant performance.

**Note:** Tested with 3D printed specimens.
Polymaker™ PC-ABS is a material with good surface adhesion which makes it easier to post process:

**Metallizing**
Polymaker™ PC-ABS can be metallized by deposition of a metallic layer in a high vacuum or by electroplating. In the metal deposition process, the best adhesion is achieved with aluminum, tin and copper. As protection for the very thin layer of metal, a coating of paint on the molding is recommended. In the case of electroplating, Polymaker™ PC-ABS offers the best adhesion for the electroless plating for its first layer.

**Painting**
Polymaker™ PC-ABS is well-suited for painting. To ensure a good paint finish, the surfaces must be clean (free of dust or grease). Particularly good adhesion is achieved using polyurethane-based coating systems. Unsuitable combinations of solvents in the paint system can attack the material and, depending on the stress condition of the parts, may initiate stress cracking. It is therefore recommended to contact the paint manufacturers who can supply suitable paint systems especially for PC-ABS blend.

**Welding**
Polymaker™ PC-ABS parts can be joined together by ultrasonic, vibration, friction, hot plate or laser welding. In order to achieve the best possible component quality when using ultrasonic welding, it is important to ensure a correctly formed weld seam.

**Bonding**
Polymaker™ PC-ABS parts can be bonded not only to one another, but also to other materials. This is possible using suitable adhesive glues or diffusion adhesive. Before gluing, greases and other foreign materials must be removed from the surfaces to be glued. Dry-cleaning fluid or similar cleaning agents, which do not damage the material, can be used to remove grease. Roughening and subsequently cleaning the surfaces improves glue adhesion. In the case of adhesive glues, two-component adhesives based on epoxy and silicone resins and polyurethanes have proved excellent.
Material Development

If your application requires a specific material that is not yet available in the market, consider our custom development service. With our talented material scientists and application engineers, we are ready to develop the needed material to enable your unique application.

Our state-of-the art R&D facilities, allow us to engineer materials at different levels and fully optimize them for 3D printing. Our goal is to deliver materials with right combination of properties/functions, processability and form to suit your needs!

About Polymaker

Our Values

Customer Oriented  Responsible  Entrepreneurial  Embracing Innovation

Mission

Polymaker is committed to lowering the barriers to innovation and manufacturing, by continuously developing advanced 3D printing material technologies for industries and consumers.
